Radiographic Imaging And Exposure 4th

Radiography is an imaging technique using X-rays, gamma rays, or similar radiation to view the internal form of an object. To create the image, a beam of X-rays or other form of electromagnetic radiation is produced by an X-ray generator and is projected toward the object. A certain amount of the X-rays or other radiation is absorbed by the object, dependent on the object's density and ...

The selection of milliamperage and exposure time, collectively known as mAs directly affects the total quantity of radiation produced during an exposure. Proper mAs selection is one of the most effective ways to yield properly exposed radiographs and reduce patient dose. It is then important to make sure that the amount of time that radiation is being emitted from the x-ray tube matches the ...

The first radiographs (X-ray images) were made by the action of X-rays on sensitized glass photographic plates. X-ray film (photographic film) soon replaced the glass plates, and film has been used for decades to acquire (and display) medical and industrial images. Gradually, digital computers gained the ability to store and display enough data to make digital imaging possible.
